I ka wā ma mua: The value of a historical ecology approach to ecological restoration in Hawaiʻi

By Natalie Kurashima*, Jason Jeremiah, and Tamara Ticktin

Abstract
Human activity has altered nearly every landscape on earth, and ecological restoration to repair degraded ecosystems has become a conservation necessity. Hawaiʻi is a microcosm for intense landscape change, where levels of native biodiversity and threats to it are among the highest in the world, and where Kānaka Maoli (Hawaiʻi’s indigenous people) who stewarded these lands for a millennium currently face massive inequalities. Consequently, biocultural restoration has emerged as a method to reciprocally restore ecological and cultural integrity, and is especially applicable in Hawaiʻi’s sizeable invasive-dominated areas. Since Kānaka Maoli are an inseparable part of every land and seascape in Hawaiʻi, any ecological restoration project has the potential to use a biocultural restoration approach. However, most restoration approaches are purely ecological, and for many conservation practitioners, a socio-cultural understanding of the landscape can seem inaccessible. In this paper, we discuss the value of a historical ecology approach—understanding the interaction between people and landscapes over time—for successful restoration and management of biocultural landscapes in Hawaiʻi. We use a case study in Kahalu’u, Kona to outline historical ecology methods and available resources in Hawaiʻi, including written documents, maps, imagery, archaeological studies, and interviews, and discuss applications of this approach on-the-ground. Potential benefits of employing this approach include: expanding knowledge of reference conditions, understanding practices contributing to landscape function over space and time, and building meaningful relationships to engaging community around a site. We argue that a historical ecology approach is readily adoptable into ecological restoration in Hawaiʻi, especially in its human-dominated landscapes.

This early view paper has been peer-reviewed and accepted for publication in Pacific Science. However, it has not been copy-edited nor has it undergone typesetting for Pacific Science. The final published paper will look different due to formatting changes, but scientific content will remain the same.
Introduction

Human activity has altered almost every part of the planet through landscape transformation, anthropogenic climate change, altering biogeochemical cycles, and changing biotic compositions through harvesting of species and by facilitating species invasions (Chapin et al., 2000; Vitousek et al., 1997). Globally, this has led to unprecedented natural ecosystem degradation (Steffen et al., 2007). The Hawaiian Islands represents an example of intense landscape change. Hawai‘i has some of the greatest rates of endemism in the world, with about 90% of the native Hawaiian flowering plant species found nowhere else in the world (Eldredge and Evenhuis, 2003). However, it is also deemed the “extinction capital of the world,” with 40% of all native Hawaiian flora currently listed as threatened or endangered (Sakai et al., 2002; U.S. Fish and Wildlife Service, 2010), two-thirds of the native land bird species extinct, and over half of the existing native birds considered threatened or endangered (Banko et al., 2001).

Accordingly, ecological restoration projects which seek to repair degraded ecosystems are growing across the archipelago, directed by federal, state, private, and community groups. Since the limited funding available is often channeled towards areas with the highest biodiversity value, most large-scale ecological restoration projects are focused in conservation zones with intact systems, from reef and coastal ecosystems to cloud forests. However, more than half of Hawai‘i’s lands exist outside of formally protected conservation areas (DBEBT, 2015), and are concentrated in lowland areas, which are often human-dominated landscapes, heavily dominated by alien species.

Just as dire as the ecological situation in Hawai‘i, is the related socio-economic conditions of Hawai‘i’s indigenous people who stewarded these lands and seas for almost a millennium (Athens et al., 2014). Similar to other indigenous peoples also under foreign influences and subsequent U.S. colonial occupation, Kānaka Maoli (indigenous Hawaiians and
their descendents) have been systematically dispossessed and separated from their ancestral territories and associated knowledge (Kameʻeleihiwa, 1992; Kelly, 1994), and currently face immense sociopolitical challenges and inequalities, including disproportionately high rates of poverty, homelessness, health problems, abuse, and incarceration (Kamehameha Schools, 2014; Kana’iaupuni et al., 2005; Moy et al., 2010). From an indigenous perspective, the health of a landscape is inherently and reciprocally connected to the health and well-being of its people (Kimmerer, 2011); thus, ecological restoration of ecosystems and cultural restoration require one another. Kimmerer (2011: 259) defines the concept of biocultural restoration as “the mutually reinforcing restoration of land and culture such that repair of ecosystem services contributes to cultural revitalization, and renewal of culture promotes restoration of ecologic integrity.”

Ecological restoration can restore the cultural and community health of people in a number of ways including: reconnecting people with ancestral practices and traditions, revitalization of traditional ecological knowledge and language, and reconnection with cultural identity and spirituality (Kimmerer, 2011; Pascua et al., 2017). Stemming from this worldview that community health is directly and inherently tied to ecological health, biocultural restoration projects have recently emerged in Hawaiʻi and elsewhere as a method to repair degraded ecosystems and cultural landscapes in concert with healing the relationships and practices of people to those places. In Hawaiʻi, these projects are often initiated by Kānaka Maoli individuals, communities and organizations, and represent an effort to regain of self-determined socio-ecological resilience on ʻāina (land and sea) today. The Society of Ecological Restoration (SER) also recognizes this view that some systems require the parallel restoration of the ecosystem with the linked indigenous management regimes, languages, and traditional ecological knowledge (TEK), and where ecological restoration is especially contingent on lasting involvement of local communities (SER, 2002).
In Kānaka Maoli cosmologies, Kānaka come from the same entities that create the earth, the sky, the stars, and all living things in the sea, on land, and in the atmosphere (Beckwith, 1951; Kamakau, 1991; Kameʻelehiwa, 1992; Malo, 1951; Oliveira, 2014), and are thus kin with all of the elements of their surroundings. From this perspective, Kānaka Maoli and their ancestors are a fundamental and inseparable part of every landscape in the archipelago, and any ecological restoration project within Hawaiʻi from the oceans to the mountain summits, has the potential to be considered biocultural and utilize a biocultural restoration approach.

Despite this, most ecological restoration projects within Hawaiʻi, like many around the world, take a purely ecological approach to restoration, relying solely on biophysical research, targets, monitoring, and success (Wortley et al., 2013). Furthermore, in many areas in Hawaiʻi, communities have not had access to or interaction with some ancestral landscapes for generations, and consequently for land managers and restoration ecologists working to restore those areas, a socio-cultural understanding of the ecosystem can seem inaccessible. However, the relatively new science of historical ecology offers an approach to understanding the interaction between people and landscapes over time, which can be readily utilized in restoration ecology to achieve outcomes of ecological health and community well-being. A purely ecological restoration effort has many benefits, but a historical ecology approach is particularly useful in human-dominated landscapes where intense landscape changes have occurred and/or where a local community is still present but has lost access. The former tend to be last priority for restoration projects, but which cover large areas in Hawaiʻi. In this paper, we explore the advantages and potential outcomes of using a historical ecology approach in ecological restoration in Hawaiʻi. We draw on a case study in Kahaluʻu, Kona to outline historical ecology methods and available resources in Hawaiʻi, and illustrate the potential benefits of integrating into the restoration and management of a biocultural landscape.
Why use a historical ecology approach in ecological restoration?

Historical ecology, a relatively new field, founded from the disciplines of anthropology, geography, ecology, history, sociology, and geography (Balee, 1998), seeks to understand environmental change over time in a socio-ecological landscape in order to inform the future (Crumley, 1994; Egan and Howell, 2001). Historical ecology has a few main tenets including, 1) humans have affected nearly every landscape on earth, which affects present-day landscape spatial distributions, 2) landscapes are the result of dynamic interactions between environment and human culture, and 3) understanding landscape change in the past should be utilized to address current and future concerns (Armstrong and Veteto, 2015; Egan and Howell, 2001). Using a historical ecology approach involves drawing from a variety of documentary and natural historical sources, such as archaeological and ethnohistoric surveys, archaeobiological studies, oral histories, historic maps, written accounts, surveys, and climate records to better understand the past functioning of a system (Egan and Howell, 2001; Swetnam et al., 1999). These sources span a range of spatial and temporal scales, providing a long-term view of a landscape, and the process is especially mindful of the interactions humans have with the system.

Ecological restoration is “an intentional activity that initiates or accelerates the recovery of an ecosystem with respect to its health, integrity and sustainability” (SER, 2002). This requires an understanding of the composition, function, and structure of an ecosystem over time. However, sometimes restoration ecologists fail to recognize the long-term and cultural functioning of an ecosystem, which can lead to flawed restoration and conservation approaches (Foster and Motzkin, 2003; Walter and Merritts, 2008). A historical ecology approach allows for the understanding of landscape history over space and time through a range of past reference conditions, referred to as the “Historical Range of Variability” (HRV) (Aplet and Keeton, 1999;
Keane et al., 2009). Moreover, it provides insight on the social and ecological functioning of that landscape in the past, offering clues on ways to restore that functioning into the future. The historical ecology approach does not involve selecting one specific reference condition over another within the historic range; these decisions should ultimately be guided by the specific vision of the restoration project.

A recent review of the restoration ecology literature found that most restoration projects do not use reference ecosystem targets, and most of those that did, used a control ecosystem, often the ecosystem before restoration (Wortley et al., 2013). In these cases, restoration ecologists use short-term biological studies to understand the site pre-restoration and to set reference targets. Yet, it has been shown that historical management and disturbances can alter vegetation patterns and ecosystem functioning after hundreds and even sometimes thousands of years (Hermy and Verheyen, 2007; Hightower et al., 2014). Thus, in order to understand the factors that have, are, and will drive ecosystem patterns and processes, a historical ecology approach is necessary. For example, Foster and Motztin (2003) used paleoecological data (pollen/charcoal data), archaeological evidence, ethnographic accounts, plant species distributions, and soil profile data to investigate the conservation and restoration of a unique grassland ecosystem in the American Northeast. They found that the areas thought to be native grasslands were actually derived after European contact. The grasslands were products of clearing and subsequent management by Europeans settlers, who utilized grazing, plowing, as well as fire, and the conservation of these biodiverse areas may depend on the restoration of the cultural practices that once maintained these landscapes (Foster and Motzkin, 2003). This example shows that to understand and manage present-day ecological conditions, it can be necessary to understand the long-term biological and cultural processes within the landscape over time. Often this requires an understanding of the ecosystem prehistorically, or before
indigenous and/or Western management of the landscape, as well as during and after these management regimes, to identify how cultural management has and will influence ecological patterns.

With climate change predicted to alter global and local weather patterns in unprecedented ways and at unpredictable rates this century (IPCC, 2007), some landscapes may shift outside of their historic ranges, signifying that historical sources alone cannot determine restoration targets (Harris et al., 2006). However, an understanding of historic conditions, changes, and ecological responses within the landscape to past climate changes still provides critical information on both past resilience and adaptability of components of the ecosystem, which can be applied to managing for resilience of a system into the future (Millar and Woolfenden, 1999; Hotchkiss et al., 2000). In addition, although there is uncertainty around ecosystem shifts under climate change, there are increasingly more climate envelope models available that predict species shifts under local climate change projections (for Hawai‘i see Fortini et al., 2013, 2015; Kurashima et al., in prep.; Vorsino et al., 2014). These models can be utilized to identify species that are predicted to shift into restoration areas, or to include species that may aid in mitigating shifts (Harris et al., 2006).

A historical ecology approach is especially relevant in Hawai‘i. The expression “I ka wā ma mua, ka wā ma hope,” can mean “through the past is the future.” Here, the past or “ka wā ma mua,” can literally be translated as “the time in front”, while the future, “ka wā ma hope,” can mean “the time behind.” This positional perspective provides insight to the Kānaka Maoli worldview, that one is always looking towards the past, seeking guidance from ancestral knowledge to address the issues of the future (Kame‘eleihiwa 1992: 22). It serves as a constant reminder to first look to the knowledge, values, and approaches of kūpuna (ancestors) when faced with any matter in today’s changing contexts. This perspective still holds true today, with
numerous Kānaka Maoli educational programming and resource management programs emphasizing traditional knowledge applications to current issues like climate change and water scarcity. The principal ideas of the field of historical ecology, namely that a generational, long-range understanding of the past is necessary to address issues today, are already embedded within the Kānaka Maoli worldview.

Second, a plethora of socio-ecological knowledge is currently stored within local Hawaiian communities, as well as in Hawai‘i’s documentary archives, including ‘ōlelo Hawai‘i newspapers, oral histories, and anthropological studies. Knowledge of ecosystems and human interaction with these ecosystems are especially deep in Hawai‘i, where despite widespread colonization, many Kānaka Maoli families have continuously carried out cultural practices such as subsistence fishing, farming, and gathering over numerous generations (McGregor et al., 2003). Additionally, much traditional ecological knowledge is stored within place names, mele (songs and chants), and mo‘olelo (stories), all serving as vehicles for intergenerational transmission of socio-ecological knowledge within communities (Kana‘iaupuni et al., 2005; McMillen et al., 2014; Näone, 2008). More recently, there has been a renaissance in relearning practices, place names, and associated knowledge systems especially in younger generations (Goodyear-Kaʻōpua, 2013; Paglinawan and Paglinawan, 2012; Tengan, 2008). Furthermore, many of the aforementioned documentary resources are already utilized and compiled by archaeologists and anthropologists in the form of ethnohistoric or cultural impact studies utilized in cultural resource management in Hawai‘i, although in many cases where the researcher does not have the capacity to read and translate ‘ōlelo Hawai‘i, these documents are often not included. Additionally, many sources have been digitized and are now freely available online (i.e., databases like Pakakilodatabase.com, AVAKonohiki.org, and Ulukau.org), although many more sources wait to be digitized.
Third, while many large landowners and conservation agencies do not use a historical ecology approach in ecological restoration, there are many smaller community and grassroots groups that have interest in and are utilizing traditional and local ecological knowledge in landscape restoration. These small-scale groups are often extremely successful in gathering and organizing people around a site and project. Given that many large conservation areas are on state or private lands and can be remote in nature, these restoration projects may not have a community living in or near it currently. Using a historical ecology approach could provide one method to begin to scale up community engagement around restoration and place. Although the goals of a large-scale restoration project may be very different from that of a community-based project, both can utilize a historical ecology approach based on ancestral knowledge, which can then serve to connect a community or a set of volunteers to a place. Given limited conservation funding, only with the help and commitments of local communities to restoration (Leigh, 2005), will it be possible to extend restoration efforts into large tracts of human-dominated landscapes across Hawai‘i.

**How can historical ecology be integrated into restoration initiatives in Hawai‘i?**

**Case Study: Informing the restoration of Kūāhewa, Kahalu‘u, Hawai‘i Island**

We present a case study of a restoration project in Kahalu‘u, Hawai‘i Island to provide an example of historical ecology methods and sources, and how they can be can be applied to restoration. We then discuss some applications and limitations of this approach in Hawai‘i. We provide this case study as a roadmap for those who are unfamiliar with historical resources in Hawai‘i, and as a more complete resource for those who may have already utilized some of these sources in management and restoration.

*Restoration Site*
Kūāhewa is a 347-acre parcel located in the district of North Kona in the ahupuaʻa (Hawaiian land division) of Kahaluʻu on the leeward side of Hawaiʻi Island. Vegetation surveys (Kurashima, 2016) revealed that the site is heavily invaded with alien plant species, with very few native species. However, almost half of the site’s canopy is made up of the native ‘ōhiʻa (Metrosideros polymorpha), more concentrated in the mauka (upland) section of the site, which boarders a predominately native forest reserve (Kurashima, 2016; Kurashima and Ticktin, in prep). The site was recently “rediscovered,” when a 2000 survey revealed over 3,500 archaeological features within the project area, which are almost all (98.7%) categorized as traditional Kānaka Maoli agricultural features (Rectman et al., 2003; Monnahan et al., 2015). The Kahaluʻu Field System is arguably the largest intact remnant of the Kona Field System (Rechtman et al., 2003), a culturally important productive complex of rain fed fields that stretched over 140km² that traditionally integrated a variety of crops, along with native plant species. The rain fed system in Kahaluʻu was farmed in the time before Western contact (1778) and the decades following by Kānaka Maoli. Since then, the site has not been actively managed, and is seldom accessed, usually by a few for subsistance hunting.

Kūāhewa is similar to other large areas that are either privately or state managed, where the associated community that lived in the area may have been displaced, maybe many generations prior. Consequently, the families that were once apart of Kūāhewa have not been allowed to consistently maintain their practices in this area, and thus have lost the ability to continually develop their relationship with the environment of that place over time as their ancestors once did. This does not mean that this community is totally disconnected, as knowledge of this place endures in many ways, yet it does indicate that the relationship between community and place has been diminished.
Today, the landowner, Kamehameha Schools (KS), the largest private landowner in Hawai‘i with a mission focused on improving the education and well-being of Kānaka Maoli, is seeking to restore the site’s ecological and social function. As a former indigenous agroecosystem, these functions include increasing native conservation value by restoring a diversity of native habitats, as well as enhancing local food production and community resilience through establishing appropriate useful crop and plant species. However, like many systems in Hawai‘i, the site has transitioned from forest to agriculture, then back to forest, but is now alien-dominated. The degraded nature of the vegetation has left almost no living evidence of the species that naturally occurred in the area, nor the species that were cultivated historically alongside these natives. Thus, employing a historical ecology approach was necessary to begin to identify species to utilize in restoration.

Although one focus of the restoration is the reestablishment of traditional crops, there is also a large emphasis on integrating a high diversity native plant species within fields, including threatened and endangered species, as well as restoring large tracts of native forest in the mauka sections of the site. This agroecological approach is representative of Kānaka Maoli management, where native and cultivated systems were somewhat fluid and interdependent, and is also relevant today because many current and former agricultural landscapes in Hawai‘i are dominated by invasive species. KS has been working with collaborator organization, Hōʻuluʻulu Kahaluʻu, who recently initiated (January 2016) to host ʻāina-based (or place-based) educational restoration workdays with local educational groups. The voluntary workdays focus on removal of invasive vegetation, establishment of native and culturally important plants, and restoration of cultural sites. The educational experiences range from plant ecology, to the local water cycle, to landscape engineering, and cultivation practices, all from a Kānaka Maoli perspective.
Historical Ecology Methods and Sources for Hawai‘i

In 2012 we undertook a historical ecology approach in order to design biocultural restoration, set goals and metrics of success, and reconnect the surrounding community to Kūāhewa. We reviewed over 20 different types of sources (details in Table 1) in both ʻōlelo Hawai‘i (The Hawaiian Language) and English spanning from before the initial settlement of Kona by Kānaka Maoli (~mid 1200 AD) (Rieth et al., 2011) to present-day environmental data and projections of vegetation shifts under future climate change scenarios for Hawai‘i (Figure 1). Recognizing that information about the site is living knowledge, we facilitated a half-day community workshop in Kahalu‘u and conducted subsequent informal interviews with kūpuna and kamaʻāina of the area to understand plant species that are valuable to the community. Participant selection for the workshop was purposeful; invitees were those who had an in-depth relationship to Kahalu‘u and/or surrounding region through residence and were also familiar with Kona agriculture through subsistence activities and/or running Hawaiian agricultural programs. During the workshop and interviews, we discussed the study site, its history, any connections and information the participants had to the specific area, as well as recommendations for plant species to be utilized in restoration.

Many sources provided information on the native plants and crops previously planted in the area, information on planting methods and other cultural practices, descriptions of ecological and climatic patterns including weather, place names and locations, and details of the restoration of Kamehameha Pai‘ea’s upland garden in Kona called Kūāhewa. Mainly because of their older publication dates, the vast majority of the sources (n=14) are freely available online (links provided in Table 1), and thus readily accessible for use. Additionally, some sources are free at the Hawai‘i State Archives (e.g., historic photographs), or could be available for certain areas at
Applications and outcomes of Historical Ecology Approach to Restoration

Because access and activities at Kūāhewa had been limited for decades, most people within the surrounding community and at KS had little knowledge of the site beyond the archaeological and ethnohistoric studies, which provided information on the cultural sites and a historical cultural context of the broader area of Kahaluʻu and Keauhou. Therefore, as researchers and land managers tasked with restoring the socio-ecological function of Kūāhewa, the first step was to hoʻokamaʻāina, become familiar with the place. We did this through regular site visits during different times of the year across as many areas of the system that we could access, and through simultaneously gathering and reading any information we could find at multiple spatial scales, including up to the moku, or regional level. The only way to understand if the information from the sources were applicable to Kūāhewa and its restoration was to understand the characteristics and cycles of the site, through being there physically as often as
possible for as many years as possible. It was through this process of building a relationship with Kūāhewa that we were able to make appropriate and sound natural and cultural resource management decisions. For example, through understanding both the historic and observed seasonal rainfall patterns and varied vegetation within microhabitats at the site, we could time the removal of overstory invasive canopy that resulted in minimal understory growth and subsequent outplantings. Simultaneously, we familiarized ourselves with other community organizations and lineal descendants of Kahaluʻu and the surrounding area by attending community-based educational programming and workdays at nearby sites. Through working alongside and consistently showing up to workdays, we were able to establish and grow a relationship with key community members.

Since majority of the site is dominated by invasive species, we needed to understand what plant species were appropriate to restore at Kūāhewa given today’s changing environmental and social context. We developed an initial planting list of 70 species, including 37 species that were cited as previously existing in or around the project area in historical documents, a pollen survey, and our interviews. At least 8 of these species were only mentioned by community members as previously existing in the area, highlighting the value of community participation in the historical ecology approach. The list also contained useful native, Polynesian introduced, and non-native but non-invasive species, that are either currently existing on site, present in the adjacent forest reserve, or are ecologically appropriate (see Kurashima, 2016 and Kurashima and Ticktin, in prep. for full planting list). This plant list also includes 8 species that are listed as threatened or endangered, and those whose habitat is expected to be lost in some areas, but maintained within the project area (i.e., kauila [Colubrina oppositifolia]) (Fortini et al., 2013). Considering future climate change in this step is ideal as some areas may no longer be appropriate for some species, while other areas may become suitable in the near future and can be considered for current
outplantings. Climate envelope models for every native Hawaiian plant species are available for
the archipelago (see Fortini et al., 2013), as well as for Polynesian introduced crop and crop
mixes (see Kurashima, 2016).

Using a historical ecology approach in the creation of the plant list resulted in recognizing
and documenting the historical preferences of the community of Kūāhewa. Historical sources as
well as the interviews with the community provided information on crops and plants that have
been and are likely to be the most important to the resource stewards of Kahaluʻu over time,
helping us to understand the community’s vision for specific plant species restoration. With the
broad planting list for the study area, we were then able to plan detailed plant mixes for specific
sites, and develop resource management goals (i.e., restore one-third of all previously mentioned
species (n=12) by the third year of restoration).

Another step in the revitalization of Kūāhewa was to restore the identity of the place.
One example is the name of the system itself, which previously termed at KS, “Kahaluʻu Field
System.” Yet, after gathering the moʻolelo of Kamehameha Paiʻea’s restoration of a vast upland
farm his people called, Kūāhewa, in historic Hawaiian language newspapers and other sources,
we reestablished the name of Kūāhewa and its associated history and mana (power; energy) at
the site. The historical ecology approach also yielded many names of places, land divisions,
cultural sites, planting methods, winds, and rains which are used during any management or
education concerning the site. Restoring these names also in turn restores the function to these
places and phenomena in the way that the kūpuna of Kūāhewa once knew them. For example,
we developed an ‘ oli kāhea (chant asking for permission) specific to the site, first honoring the
area through calling out the names for the water cycle and land boundaries, then recognizing
Kamehameha’s historical restoration of the area with his people. Finally, the ‘ oli acknowledges
the current generation of stewards of Kūāhewa and their purpose to replant and restore for
Kūāhewa’s sustainability into the future. In many places, it may be more appropriate to continue
process of haku mele (composition) about an area or process to reflect and honor the place and
its function in today’s context. By speaking these traditional names again and echoing them
throughout Kūāhewa; by creating an ‘oli to honor Kūāhewa, this generation of resource stewards
affirms themselves to the place in a way that the kūpuna who cared for this place generations ago
once did. The value does not lie only in the specific content of names or information uncovered,
but in the process of using that knowledge again, which then returns the purpose and function to
that knowledge.

Due to the dense vegetation in some areas, it was difficult for anyone, both managers and
visitors, to access many of the cultural sites and restoration areas. We established interpretive
trails of sites using the archaeological studies and the help of an archaeologist familiar with the
restoration area. Using the historical resources, we selected characteristically common Kona
Field System sites, along with sites unique to Kahaluʻu, then designed an easily accessible trail
to these sites. We also developed a narrative for each location, highlighting information from the
historical record, such as specific planting methods and types of crops planted at the site. The
development of the interpretive trail has allowed for better access for targeted resource
management (native plant, crop, and cultural site restoration). Starting with a relatively small
number of sites (around 15) and connecting trails helped us to set achievable goal for initial
invasive species removal, cultural site restoration, and native replanting. Furthermore, we used
the interpretive trail each time a visiting group visits as a way to introduce volunteers to a wide
variety of restoration areas quickly and easily, serving as a way for people to build pilina
(connection, relationship) with Kūāhewa.

Due to limited access to Kūāhewa for generations, we needed to reopen and reestablish
relationships between the surrounding community and Kūāhewa as well between us as resource
managers and the community. With a specific outplanting plan, established interpretive trails and narrative, we were able to host visitors, which included community members, students, contracted crews, researchers from local universities, other natural resource managing organizations, and groups from within KS, in a much more meaningful way. The historical ecology approach provided us with a trove of information, which we shared with all visitors either in conversation, or through visuals such as large durable historic maps. The maps operate at different scales to explain both the specific adaptations of Kānaka Maoli practices to a sites as well as broader landscape patterns across the island. The maps help individuals place themselves within the landscape over space and time, and also serve to establish pride and a connection to the ingenuity of the kūpuna who once managed Kūāhewa. Sharing the information from the historical ecology approach and resulting narrative is also a way to show the community our respect for the site and for them –i.e., a form of reciprocity. Learning as much as possible through the historical ecology approach and physical presence served as an indicator to some of the kūpuna, who have knowledge of the area, that we had “done our homework.” It was a way to demonstrate how much we valued Kūāhewa and valued the time we had with the kūpuna of the place, because it was only after years of the research process and subsequent increased understanding of the place over time that we were able to ask them meaningful questions that could then in turn help to drive restoration.

With the numerous hands on site, we were then able to work towards the restoration of many of the Kānaka Maoli practices associated with Kūāhewa. One example was our efforts to revitalize various planting methods and techniques discussed in historical documents. One site we cleared on the trail consists of built-up planting rings in an area that is intermittently filled with standing water. This site was considered unique, and is not known by the archaeologist to exist in other parts of the Kona Field System. We reestablished the name of mākālua, which
refers to planting in mulched holes, pits (Handy et al., 1972) to this site. A group of local and Kānaka Maoli students from the surrounding area filled these mākālua with soil and mulch derived from the surrounding invasive species and planted huli (cuttings) of kalo (*Colocasia esculenta*; taro) that they brought from their garden, while we all chanted an ‘ōli associated with planting. The act of bringing kalo huli and putting their hands into the soil is also a form of reciprocity between those Kānaka and Kūāhewa. Though the varieties of kalo, the type of mulch, and the chant may or may not be exactly what was used traditionally, the value lies in the process of returning the function to the mākālua and the function to the collective community as the stewards of this place. The tradition also continues in the monitoring and continued relationship of these students to with these outplantings over the year and experimenting with better ways to ensure the continued growth of these crops, just as the kūpuna of Kūāhewa once did. By reestablishing the succession of planting, the succession of stewardship of Kūāhewa, this generation of stewards becomes part of the moʻokūʻauhau, the genealogy of the place. In this way, we as the collective stewards (resource managers, researchers, students, community members) will always be tied to and will always have a kuleana (responsibility) to this place.

**Discussion**

Our case study focused on restoration of an agroecological site, including both forest and agriculture systems, but our approach is applicable to restoration of forests or other natural ecosystems in Hawaiʻi. Our site has not been occupied for generations and did not have a specific community tied to it through practice. In this way, it is comparable to some of the more remote areas of Hawaiʻi, where Kānaka once had a more constant relationship with, but have since been displaced. In these areas, a historical ecology approach can serve as the first step in a
biocultural restoration process to ultimately can aid in reestablishing relationship between resource stewards, including the community, and the place.

As we showed, there is a wide variety of freely available resources that can be a critical part of restoration. One of the most important applications of historical resources is in helping to determine reference conditions in landscape restoration, which can often help to then generate species lists for outplanting. Because restoration goals were biocultural—to restore the ecological and the Kānaka Maoli cultural system and their interconnections, the decision was to restore to a context that emphasized both. Therefore, many of the reference conditions chosen were during the time of the cultivation of the Kona Field System (~1300-1900) (Allen, 1991). Yet, we did include reference conditions from pre-contact and information about future climate change into our resulting plant list. Even if the reference conditions for restoration are pre-Polynesian management, a historical ecology approach can still be used to both determine this earlier range of historical variability, and to provide information on landscape change over time. For example, the archeobotanical study indicated the previous presence of native species not found in the surrounding forest nor mentioned by the community. Their current absence from the greater area and absence in the mind of some of the people of the place could indicate long-standing changes to their recruitment.

In addition, plans for the reference condition can shift over time. For example, in our case defining the reference condition has been, and will continue to be, a collective and iterative process. For example, though we have a planting list of ecologically and culturally appropriate species that guides outplantings, groups continually bring seedlings as makana (gifts) to the site. Often, they will ask what is appropriate and we provide the list, but other times they will bring what they feel is appropriate. Although a historical ecology approach can provide a guide,
ultimately, it is the decision of the (collective) stewards of a place to decide on the most appropriate reference condition(s).

Our case-study illustrates that this approach can be used to provide guiding principles for appropriate restoration, both ecologically and culturally, and aid in setting social and cultural goals of restoration alongside biological ones. It also demonstrates how much of the information gathered in a historical ecology approach can be shared with restoration participants as a way to further engage them in the biocultural history of the site. These applications not only provide valuable insights about restoration to the land owner, ecologist or manager, but can serve to build relationships between community and place as well as manager to community. Kānaka Maoli scholar C. Kanoelani Nāone writes, “We sustain and grow our connection to the land by sharing stories of place. By learning the names of places we claim and opening a dialogue with ʻāina, we come to understand the deeper meaning of place” (Nāone 2008: 333). Restoration and management can facilitate these connections of communities to ʻāina by enabling both physical access to lands and just as importantly through sharing and restoring the stories, names, and history of a place. It is important to note however, a historical ecology approach does always necessitate a community-based effort, and can be utilized in restoration not driven by community.

There are limitations in both the access and utilization of some of the historic sources. First, those not freely available online have a cost, which are usually minimal, but ethnohistoric and archaeological studies can be very costly to the landowner, organization, or individual, usually costing upwards of $15,000. However, these types of studies have been executed in many areas and are publically available at the State Historic Preservation Division (SHPD) library. Archaeobotany studies, which are especially helpful in determining plant species composition over long time scales, are much less common, but have been executed in some
areas. Managers and ecologists can look for published studies done in similar ecological zones or biocultural landscapes (i.e., within a lowland mesic forest on the same island) for pertinent information. There are also a number of historic sources at the Bishop Museum, but access is limited by appointment as well as designated time restrictions for research. Another limitation is language. Many sources are solely in ʻōlelo Hawai‘i and older documents are written in colloquial ʻōlelo Hawai‘i, which requires a more advanced understanding of the language. However, with the growth of ʻōlelo Hawai‘i programs throughout the archipelago, there are many students of the language that one could employ for the task of reading, summarizing, and/or translating. Finally, some areas within Hawai‘i may have less available data than others, depending on the specific history of people on those landscapes over time. In these cases, it is important to remember that there are people who are still connected to that place and have valuable knowledge of the history of the area, who can be contacted. Although an all-inclusive picture of the history of a landscape is unachievable, failing to ignore the history of a place altogether could be perilous to the socio-ecological success of a restoration project.

With worldwide environmental degradation, ecological restoration is increasingly becoming a requirement within the field of conservation (Hobbs and Harris, 2001). There is limited programmatic funding at the government, non-profit, and community levels, especially for projects outside of formal conservation areas, and more and more projects are turning to volunteers for labor assistance to leverage costs and reach management goals. The success of restoration and conservation projects is dependent on public support and community involvement (Higgs, 2003; Leigh, 2005; Ryan et al., 2001) and this is especially true if restoration efforts are to be scaled up to the vast areas of human-dominated landscapes that lie outside of protected areas. Studies on the U.S. continent, have found that “helping the environment,” and “learning” are the most important motivations for conservation volunteers.
But, in places like Hawai‘i, where the land and seascapes are an essential part of the genealogy, identity, and well-being of its indigenous people for generations upon generations (Kana‘iaupuni et al., 2005; Nāone, 2008), motivations to volunteer are more akin to responsibilities to take care of a family member. This drive is powerful, and desires to return to ancestral lands and learn the history of place is on the rise in Hawai‘i. Biocultural restoration projects that utilize a historical ecology approach are a powerful tool to foster existing connections or in other cases, help to reestablish relationships of individuals and communities to ‘āina, potentially enabling long-term restoration success. The following quote from a community volunteer at Kūāhewa exemplifies this:

“Our people have been threatened by abuse—physical, mental, social, for generations. Our land has been abused—development, large-scale agriculture, pasture, invasive species, fire, for generations. And we continue the cycle of abuse both on the land and to ourselves as people. We have a kuleana [responsibility] to restore these Hawaiian landscapes to not only heal the land, but to heal ourselves, families, and ultimately our communities for future generations.” –Kamuela Meheula of Holualoa, Kona

In an era where most of Hawai‘i’s human-dominated lowland areas are characterized by non-native vegetation (Hawaii Gap Analysis Program, 2006), and the indigenous people of Hawai‘i face health and well-being challenges, it is now not enough to mitigate ecological threats or restore ecosystems alone. In Hawai‘i, management strategies that restore people to lands through access, cultural practices, and knowledge, is the only way to truly restore these human-dominated landscapes, and ensure the sustainability of restoration into the future. The consequences of biocultural restoration programming with an approach that truly integrates local and Kānaka Maoli communities goes far beyond achievements of biodiversity, but works towards the renewal and strengthening of people to place, their culture, and each other.
